To Adjust or Not to Adjust: A Users’ Perspective on Analysis of Economic Trends with Seasonal Data

2nd Seasonal Adjustment Practitioners Workshop

Washington, D.C., April 26, 2018

a.ozyildirim@conference-board.org
Presenter

Ataman Ozyildirim, Ph.D.

Director, Business Cycle and Growth Research, manages research on the Business Cycle Indicators program and also oversees research in Productivity, Innovation and Competitiveness, as well as on the annual Global Economic Outlook.
The Conference Board Selected Economic Indicators & Surveys

- **Monthly Indicators:**
  - US Consumer Confidence Index® Leading Economic Indexes (LEI): Australia, Brazil, Euro Area, China, France, Germany, India, Japan, Korea, Mexico, Spain, UK, US and Global Economy, Employment Trends Index™

- **Quarterly Indicators:**
  - Measure of CEO Confidence™, Global Consumer Confidence Survey

- **Other Indicators/Services:**
  - The Business Council Survey – 3x per year
  - Business & Economics Portfolio – quarterly
  - Business Cycle Indicators Database – weekly
  - International Labor Comparisons updates – periodic
  - Job Satisfaction Survey – annual

- Global Economic Outlook, labor market and consumer research
Overview: Business Cycle Indicators and Seasonal Adjustment

- Business cycles and the problem of seasonality
- Turning points and phase shift problem
- Short-term vs. long-term decision making
- Seasonal adjustment in a global economy
- Potential pitfalls: modeling and real time analysis
- Are improvements to current SA methods possible?
Regular cycles are an enduring feature of economic data….But, some cycles are more regular than others…. 

“In contrast [to regular and predictable seasonal fluctuations], recurrent slumps that generate declines in sales, production, and incomes along with rises in unemployment clearly belong to the sphere of public interest, and so do recurrent inflationary or speculative booms.”

Zarnowitz (1992) p. 262

- Sales
- Production
- Income
- Employment
Seasonal fluctuations are a common feature of most economic data

- Intra-year variation that occurs at or about the same point each year -- not necessarily regular, but easily predictable

- Usually caused by exogenous factors:
  - Weather
  - Institutions
  - Holidays (Christmas, Easter, Ramadan, Chinese New Year, etc.)

- Could account for majority of the variation in economic data

- Could be present in every type of economic activity, but not a significant feature of stock prices and interest rates

- Difficult to incorporate into formal economic models due to lack of clear theoretical foundation
Timing in trend-cycle components: leading vs. coincident indicators

LEI

The indicator approach to business cycle analysis of recurring and uniform sequences in economic activity

- Relationships between *non-seasonal* part of data is main concern in business cycle analysis
- Sequences are revealed in seasonally adjusted indicators, classified according to cyclical timing
  - Coincident, Leading, Lagging indicators
- Recurrence of these timing sequences and relationships between types of economic activity
- **Composite indexes** define and predict turning points
  - The Conference Board Coincident Economic Index® (CEI)
  - The Conference Board Leading Economic Index® (LEI)
An important note on: business cycles vs. growth cycles

- **BCP**: Business Cycle Peak
- **BCT**: Business Cycle Trough
- **GCP**: Growth Cycle Peak
- **GCT**: Growth Cycle Trough

The diagram illustrates the level of economic activity over time, showing deviations from the long-term trend with peaks and troughs labeled accordingly.
Seasonality accounts for majority of the variation in most indicators of real activity (e.g. payroll employment)

Source: Haver Analytics
Phase shift problem: Simplest seasonal adjustment often used for short term analysis smoothes the data, but ill-equipped for long-term business cycle research.
Composite indexes reveal historical business cycles

The indexes

- Bring cycles and turning points into focus
- “Real time” monitoring

- The components are
  - Seasonally adjusted
  - Deflated
  - Volatility adjusted
  - Aggregated with equal weights
Leading Economic Index summarizes and helps to predict the state of the economy and short term cyclical forces acting in and on it.

U.S. CEI shows slower than average recovery post great recession

(Trough date=100)

Source: The Conference Board. Recession dates are determined by NBER.
U.S. LEI shows volatile recovery period but no recession signal

Source: The Conference Board. Recession dates are determined by NBER.
Seasonally adjusted employment provides a better basis for understanding the depth of the recession or the strength of the recovery.

Seasonal adjustment with moving holidays: Chinese New Year has strong patterns and significant effects on China’s monthly data.

Source: Haver Analytics
The case of Brazil: series are seasonally adjusted for Carnival

Source: Haver Analytics
Religious holidays (Diwali and Ramadan) were taken into consideration when adjusting India data.

Consequences for modeling and inference

- SA could reduce data quality by introducing estimation errors
- SA could introduce
  - Spurious dynamic relationships
  - Asymptotic biases in parameter estimates of regressions
- One solution: use same seasonal adjustment filter on all variables (Sims, 1974)
- Unadjusted data could overstate dependence between variables due to common patterns in seasonal movements
Seasonality distorts real-time analysis of the underlying strength or weakness of economic trends

All Employees: Aggregate Weekly Hours

Source: Haver Analytics
Real-time analysis of economic trends is difficult, seasonality would make it doubly so

Real GDP, quarterly, real-time

Coincident Index, monthly, real-time

Source: Federal Reserve Bank of Philadelphia

Source: The Conference Board
Consequences for real time analysis

- SA could reduce data quality by introducing estimation errors
- SA could increase frequency and size of data revisions
- Adjusted data could exhibit residual seasonality, moving seasonality, vis a vis disaggregate and aggregate indicators etc.
  - Indirect SA vs. direct SA vs. double SA
- Use both NSA and SA data in current analysis
Summary

- Seasonality is a common and highly predictable feature of economic data
- Seasonal adjustment removes the predictable pattern to reveal the underlying trend and cycle
- Seasonal adjustment is necessary for business and economic analysis
- Seasonal adjustment data is needed to
  - Understand past cycles
  - Predict future cycles
- Ways to improve seasonal adjustment methods
  - Methodological/modeling improvements?
  - Big data to the rescue?
